ABSTRACT

A model for learning systems is presented, and representative AI, pattern recognition, and control systems are discussed in terms of its framework. The model details the functional components felt to be essential for any learning system independent of the techniques used for its construction, and the specific environment in which it operates. These components are performance element, instance selector, critic, learning element, blackboard, and world model. Consideration of learning system design leads naturally to the concept of a layered system, each layer operating at a different level of abstraction.

KEY WORDS

ADAPTATION, LEARNING, CONCEPT-FORMATION, INDUCTION, PERFORMANCE ELEMENT, INSTANCE SELECTOR, CRITIC, LEARNING ELEMENT, BLACKBOARD, WORLD MODEL, MULTI-LAYERED SYSTEMS.

Abstract

A model for learning systems is presented, and representative AI, pattern recognition, and control systems are discussed in terms of its framework. The model details the functional components felt to be essential for any learning system, independent of the techniques used for its construction, and the specific environment in which it operates. These components are performance element, instance selector, critic, learning element, blackboard, and world model. Consideration of learning system design leads naturally to the concept of a layered system, each layer operating at a different level of abstraction.

Descriptive Terms: adaptation, learning, concept-formation, induction, performance element, instance selector, critic, learning element, blackboard, world model, multi-layered systems.

1 Introduction

Adaptation, learning, concept-formation, induction, self-organization, and self-repair have been of interest to researchers in a number of fields for many years. Each discipline has brought a different perspective to the research, and the result has been a great...
variety of learning system (LS) models and descriptive terminology. We have therefore synthesized a new model for unified characterization of system constructed from these different perspectives. The model is also useful as a paradigm for new learning systems, because it enables the designer to isolate the functional components, and the information that must be available to them.

2 Two Approaches to Learning

In this section, we summarize two different approaches to the construction of systems that can be said to learn. The first approach centers on the concept of an adaptive system and is primarily associated with research in pattern recognition and control theory; the second is that of artificial intelligence (AI).

2.1 The Adaptive System Approach

In the control literature, learning is generally assumed to be synonymous with adaptation, and is often viewed as estimation or successive approximation of the unknown parameters of a structure which is chosen by the LS designer to represent the system under study [8] [12]. Once this has been done, control techniques known to be suitable for the particular chosen structure can be applied. Thus the emphasis has been on parameter learning, and the achievement of stable, reliable performance [30]. Problems are commonly formulated in stochastic terms, and the use of statistical procedures to achieve optimal performance with respect to some performance criterion such as the probability of correct pattern classification, or mean square error, is standard [39].

There are many overlapping and sometimes contradictory definitions of the terms "adaptive system", "learning system", "self-repairing system", and "self-organizing system". The following set, formulated by Glorioso [13] serves to illustrate the main features. An adaptive system is defined as a system which responds acceptably with respect to
some performance criterion in the face of changes in the environment or its own internal structure. A learning system is a system that responds acceptably within some time interval following a change in its environment, and a self-repairing system is one that responds acceptably within some time interval following a change in its internal structure. Finally, a self-organizing system is an adaptive or learning system in which the initial state is unknown, random, or unimportant.

Other terms often used to describe learning systems in the pattern recognition and control literature are "learning with teacher" or "supervised learning" and "learning without teacher" or "unsupervised learning" [12][7]. Learning with teacher assumes the existence of an external entity (usually a human) which presents the system with a training set of instances, evaluates the performance of the system for those instances, and provides the correct responses. Learning without teacher assumes that the environment provides all instances, but does not provide the correct responses. Performance is to be evaluated by the system itself. Tsypkin [33] has pointed out that unsupervised learning is somewhat of an illusion in the sense that a teacher/designer defines the structure which determines the quality of operation of the LS at the outset, whether or not he is present during the actual operation of the system.

2.2 The Artificial Intelligence Approach

Although early AI research was closely tied to pattern recognition, and the techniques commonly associated with the adaptive system approach, (see, for example [28] and [34]), the two fields diverged in the 1960's, and are now quite distinct. Whereas the pattern recognition and control research emphasizes adjustment of parameters, AI research emphasizes construction of symbolic structures, based on conceptual relations. For example, Feigenbaum's EPAM program [9] used a

---

3 Learning and self-repairing systems have been considered as specialized adaptive systems [30].
discrimination net (i.e., a tree of tests and branches) to store the relations required to recall nonsense syllables in a rote learning experiment (see [31], [11], and [37] for further examples).

The kind of learning that involves only estimation of unknown parameters (i.e., the parameter learning of Section 2.1) has been referred to as terminal learning in the AI literature [22]. In AI, it is commonly believed that a learning system should have sufficient internal structure to develop a *strong theory* of its environment [10] [19]. Much emphasis has therefore been placed on building "knowledge-based" or "expert" systems that not only have the capacity for high performance, but can also explain their performance in symbolic terms [6]. Concept-formation systems in particular stress the construction of symbolic descriptions [14].

Winston [38] describes various levels of sophistication in learning systems: learning by being programmed, learning by being told, learning from a series of examples, and finally learning by discovery. We see in this categorization a gradual shift in responsibility from the designer/teacher to the learning system/student. At the highest level, the system is able to find its own examples, and carry on autonomously.

3 The LS Model

We are concerned with the functional description of LS’s and their interaction with the environments in which they operate. Many of the functional components of an LS are essential to intelligent systems in general, as noted also by Simon and Lea [29].

3.1 Environment

The environment in which an LS operates may have a profound effect upon its design, and therefore it is of interest to consider a few major environment classes. LS environments can be divided into two major categories: those that provide the correct response for each training
instance (supervised learning) and those that do not (unsupervised learning). Supervised learning systems operate within a stimulus-response environment in which the desired output of the LS is available along with each training instance [12] [7]. Samuel’s "book move" checkers program [26][27], and grammatical inference programs [15] (i.e., programs that attempt to infer the rules of a grammar from sample sentences generated by that grammar) are further examples of LS’s operating within such an environment. This is also the nature of the environment for automatic programming systems [14] which construct programs to reproduce (or explain) a set of sample input/output pairs.

Unsupervised LS’s operate within an environment of instances for which the correct response is never available. The version of Samuel’s program which learns by playing checkers against an opponent falls into this category [26]. Learning systems operating within this type of environment must themselves infer the correct response to each training instance by observation of system performance for a series of instances. As a result, assignment of credit or blame for overall performance to individual responses is a problem for these systems [21].

Environments can be further categorized as "noise-free" or "noisy". Noise-free environments, such as that of Winston’s structural description learning program [37] provide instance/correct-response pairs in which the data are assumed to be perfectly reliable. Noisy environments, on the other hand, do not provide such perfect information, as is usually the case when real data are involved (pattern recognition and control systems frequently operate within noisy environments [7] [8] [1]). Environments which react to the LS responses in some way that is not under the control of the system can also be considered to fall into this category. The opponent in a game for example, operates on the response of the LS to provide the next instance [35].
3.2 The Model - Overview

The LS model is shown in Figure 1. The PERFORMANCE ELEMENT is responsible for generating an output in response to a training instance. The INSTANCE SELECTOR selects suitable training instances from the environment. The CRITIC analyzes the output of the performance element in terms of some standard of performance. The LEARNING ELEMENT makes specific changes to the system in response to the analysis of the critic. Communication among the functional components is shown via a BLACKBOARD to ensure that each functional component has access to all required system information. Finally, the LS operates within a WORLD MODEL containing general assumptions and methods defining the domain of activity of the system.

Existing systems can seldom be partitioned unambiguously into the functional components shown in Figure 1. These components are conceptual entities which simplify the characterization of existing systems, and will assist designers in the construction of new systems. They correspond to functions that must be performed to effect learning. In many existing systems, one or more of the functions are fulfilled by a human who is considered to be part of the LS.

In the following sections, we present detailed discussions of the LS model components shown in Figure 1. In addition, Appendix I contains detailed characterizations of representative AI, pattern recognition, and control systems in terms of the model. The reader may find it helpful to refer occasionally to this appendix while reading the following sections.
3.3 Performance Element

The performance element is the mechanism that uses the learned information to perform the stated task. It has been included in the LS model because of the intimate relationship between what is to be learned by an LS and the way in which the learned information is to be used.

Performance elements are usually tailored more to the requirements of the task domain than to the architecture of the LS. In general, the performance element can be run in a stand-alone mode without learning, independent from the rest of the LS (e.g., Samuel's checker playing program \[26][27]). In any LS, however, the ability to improve performance presupposes a method of communicating learned information to the performance element. Therefore, the architecture of the performance element must allow learned information to affect its decisions, and so additional constraints are placed on any performance element that is to be used as a component of an LS. The performance element must be
constructed so that information about its internal machinations is readily available to the other system components. This information can be used to make possible detailed criticism of performance, and intelligent selection of further instances to be examined by the system.

The performance elements of existing systems vary in the number of ways in which they may be altered by learning. Systems which adjust parameters as their sole learning method are relatively limited in the performance variations they can exhibit [17][20], whereas systems whose operation is determined by a set of production rules can exhibit greater variations [35][36].

3.4 Instance Selector

The instance selector is a mechanism that selects training instances from the environment that are to be used by the system in learning. It is a functional component not clearly isolated in earlier adaptive system models [12][30][13].

In reviewing existing LS’s we have found that methods for instance selection vary mainly along the dimensions of responsibility and sophistication. The responsibility for instance selection varies between the extremes of completely external ("passive") selection, and completely internal ("active") selection. Instance selection in Samuel’s book move checkers program [26][27] is externally controlled, whereas Popplestone’s program [24], which learns the features that characterize a winning position in tic-tat-toe, generates its own training instances. It forms alternate hypotheses, and then generates instances to choose among them (relying upon an external critic to evaluate these instances). In the adaptive systems literature, Tse and Bar-Shalom [32] discuss the use of "dual-control" in an attempt to identify the parameters of a system at the same time as it is being controlled.

The degree of sophistication used for LS instance selection is also an important consideration. In order to qualify as sophisticated,
an instance selector must be sensitive to the current abilities and deficiencies of the performance element and must construct or select instances which are designed to improve performance. Winston [37] has shown the advantages to be accrued through presenting carefully constructed examples and “near-misses” of the concepts to be acquired by an LS. In general, careful instance selection can improve the reliability and efficiency of an LS. We must note, however, that this may not always be permitted by the environment in which the LS operates, as is generally the case for adaptive control systems [8].

3.5 Critic

The critic may play three roles; EVALUATOR, DIAGNOSTICIAN, and THERAPIST. It always operates as an evaluator, in that it embodies a standard by which to assess the behaviour of the performance element. This is the role that has been emphasized in earlier adaptive system models [12] [30] [13].

The critic may also operate as a diagnostician, and localize the reasons for poor performance. This type of behavior is essential for resolution of the credit assignment problem described by Minsky [21]. In its role as diagnostician, the critic is exemplified by the bug classifier and summarizer in Sussman’s HACKER [31].

Finally the critic may be able to operate as a therapist, and make specific recommendations for improvement or suggestions about future instances. In Waterman’s poker player [35], the critic as therapist suggests the bet that should have been made by the performance element for a particular training instance.

Not all systems exhibit sufficiently complex behavior to warrant critics that fulfill all three functions. The critic as therapist in particular is not often seen in simple systems.

The dividing line between critic and learning element is difficult to distinguish, and it is certainly possible to view therapy as a
function of the learning element, rather than one of the critic. However, in mapping existing LS's into our model, we have adopted the convention that the critic's recommendations to the learning element are at an abstract level removed from the implementation details such as data representation.

In some LS's the functions of the critic have been left to the human who uses the system. For example, MYCIN/TEIRESIAS [6] uses a human critic, acting as evaluator, diagnostician, and therapist to suggest alterations to its rule base.

3.6 Learning Element

The learning element is an interface between the critic and the performance element, responsible for translating the abstract recommendations of the critic into specific changes in the rules or parameters used by the performance element.

Representations for learned information exhibit great variety. They include, for example production rules [35], parameterized polynomials [26], executable procedures [31], signature tables [27], stored facts [9], and graphs [37]. The method of incorporating new learned information is dependent upon this representation, and even among systems which use similar representations, competing methods are found (contrast, for example, [3] and [35]).

The extent to which the learned information is altered in response to each training instance is an important LS design consideration. In some systems [37], the learning element incorporates exactly the information supplied by the critic. Were the same training instance to occur later, the response of the performance element would be exactly as the critic advised for the first occurrence. This type of learning is well suited to environments which provide perfect data and to systems with reliable critics. Under these conditions the LS will converge rapidly toward the desired behavior. If such a system were provided with an incorrect classification by the environment or less than
reliable advice by the critic, however, it might commit itself to incorrect assumptions from which it is difficult to recover. Systems which make less drastic changes to the learned knowledge on the basis of a single training instance are less vulnerable to imperfect information, but consequently require more training instances to converge to the desired behavior. Many statistical LS's fall into this category [23]. Other systems consider several training instances at a time in order to minimize the effect of occasional noisy instances [3].

3.7 Blackboard

The blackboard of our model is an extension of the concept introduced in the HEARSAY system [18], functioning as both global data base and communications mechanism. The blackboard holds two types of information: --the information usually associated with the "knowledge base" in AI programs, and the temporary information used by the LS components. The knowledge base often contains the set of rules, parameter values, symbolic structures, and so on, currently being used by the performance element. Such information can be used as an aid to sophisticated instance selection if it is readily available. The temporary, system-oriented information includes, for example, the internal decisions made by the performance element in selecting a particular response. Detailed criticism by the critic is dependent upon the availability of this information, written by the performance element.

In many existing systems this information is not so clearly separated or defined. The communication links between functional components, especially, are often programmed directly. Such a non-modular approach is known to lead to difficulties when redesign is attempted [2].

3.8 World Model

Whereas the blackboard contains information that can be altered by
the LS components, the world model contains the fixed conceptual framework within which the system operates. The contents of the world model include definitions of objects and relations in the task domain, the syntax and semantics of the information to be learned, and the methods to be used by the LS. Again, there are no clear lines of separation between the world model and the other parts of the LS. Our working definition is that the world model contains all definitions, parameters, vocabulary, and assumptions that are available for modification. (Insofar as the designer can change any piece of the LS we suggest separating those that are easily modified from the rest. See [25] for a philosophical treatment of this issue, and [5] for the discussion that led to our including a world model.) Among task domain definitions are, for example, the rules of a game, and the representation of inputs and outputs for the performance element. This part of the world model simply defines the task of the performance element, and the standard of performance (the evaluation function) to be applied by the critic. Definitions of the syntax and semantics of information to be learned define the mode of communication between the learning and performance elements.

The world model may include several additional items. Some systems require a model for translating input data into the specific training instances to be used. For example, the controller in [17] preprocesses inputs in a control system, and the first part of MetaDENDRAL [3] translates each input molecule/data-point pair into plausible molecule/process pairs under a simple theory of the task domain. Domain specific heuristics are also commonly added to the world model of AI systems to guide inferences made by the LS (e.g., the blocks world heuristics of Winston's program [37]).

Although the world model cannot be altered by the LS that uses it, the designer can alter its contents in order to improve LS performance. He often changes parameters and procedures of the basic LS after observing and criticizing its behavior for some carefully chosen
training set. These alterations result in a new version of the LS, which is then tested on some training set, and so on. The designer views the whole LS as a system whose performance needs improvement, and he selects instances, criticizes performance, and makes changes accordingly. In other words, the designer’s activities can be modeled by a system whose components are just those in Figure 1. This leads us to the concept of layered LS’s, each higher layer able to change the world model (vocabulary, assumptions, etc.) of the next lower layer on the basis of criticizing its performance on a chosen set of instances. Thus, adjustments can be made to the world model of some learning system LS1 by another learning system, LS2, which has its own functional components (critic, world model, etc.). In turn, it is conceivable that a third system, LS3, could adjust the world model of LS2, and so on. The final critic, however, is the designer, operating outside of the "top-level" LS.

One existing LS which may be viewed as a layered system is the version of Samuel’s program [27] which learns a polynomial evaluation function for selecting checkers moves (see Appendix I for details). The lower layer (LS1) in this system adjusts the coefficients of a given set of game board features in order to improve performance of the move selection program. The second layer system (LS2) adjusts the set of board features used in the evaluation function in order to improve the learning performance of LS1. Since LS1 is contained in LS2 as the performance element, all the assumptions necessary for its operation also belong to the LS2 world model. In addition, the LS2 world model contains assumptions about the set of allowable game board features and the standard for evaluating LS1 performance.

A single layer LS, then, can never move outside its world model to make radical revisions to its way of viewing the task to achieve a "paradigm shift", as discussed by Kuhn [16]. However, a shift in the conceptual framework of LS1 could be made by a properly programmed LS2 [3]. We believe that a layered approach such as that described above
provides a useful system organization for learning at various levels of abstraction in complex domains. Although there are examples of this kind of layering in the literature [26][34], no one has carried it as far as our model suggests, and it appears that we are just now reaching the point of understanding single layer learning systems well enough to consider developing more sophisticated systems.

4 Summary

The proposed LS model provides a common vocabulary for describing different types of learning systems which operate in a variety of task domains. It encourages classification and comparison of LS's and helps identify unique or strong features of individual systems. We believe the model is a useful conceptual guide for LS design, because it isolates the essential functional components, and the information that must be available to these components. The model also suggests a layered architecture for learning at different levels of abstraction.
Appendix I
Characterization of Existing Systems in Terms of the Model

In this appendix several existing LS's are characterized using the framework provided by the model described in Section 3. The systems selected are representative of several approaches to machine learning. Because the blackboard contains information in a state of flux, its contents are not specified explicitly for the systems characterized below.

**Meta-DENDRAL, Buchanan, et al, [3][4]**
Domain: Mass spectrometry.
Purpose: Learn to predict data points in the mass spectra of molecules.
Environment: Set of all known molecule/data-point pairs.
Performance Element: Predicts peaks (data points) in mass-spectra of molecules using learned production rules. Employs a model of mass spectrometry for translating between mass-spectral processes (predicted by the rules) and data points in the spectrum.
Instance Selector: Accepts a set of known molecule/spectrum pairs from the user.
Critic: Evaluation - determines the suitability of the set of predictions generated by a rule. Diagnosis - states whether the rule is acceptable, too specific, or too general. Therapy - recommends adding or deleting features to the left-hand sides of rules.
Learning Element: Conducts a heuristic search through the space of plausible rules using a predefined rule generator. At each step in the search the potential rule's performance is reviewed by the critic.
World Model: Representation of molecules as graphs, production rule model of mass spectrometry, vocabulary of rules used to represent learned information; heuristics used by the critic in directing the rule search.

------------------

Program to Learn Structural Descriptions from Examples, Winston [37]
Domain: Blocks world.
Purpose: Learn to identify blocks world structures (such as arches and towers).
Environment: Set of possible line drawing/structure-classification pairs.
Performance Element: Decides class of structures to which the input structure belongs. Uses a model of the structure class supplied by the learning element.
Instance Selector: Accepts training instances supplied individually by the user.
Critic: Evaluation - compares the classification made by the Performance Element against the correct classification as supplied with each training instance. Diagnosis - generates a comparison description pointing out differences between the model and the structure description.
Learning Element: Constructs a model of the class of structures under consideration. Examines the comparison description supplied by the critic, and modifies the model to strengthen or weaken the correspondence between the model and the training instance.
World Model: Representation of scenes as line drawings, method of translating line drawings to graphical descriptions, grammar for representing the learned information, domain-specific heuristics for resolving among possible changes to each structure class model.
Checker Player, Samuel [26][27]

Domain: Game of checkers.

Purpose: Learn to play good game of checkers (here we discuss only the version of the program which learns a linear polynomial evaluation function by examination of moves suggested by experts ("book moves").

Environment: Set of all legal game boards,

LS1 (lowest layer):
Purpose: Learn a good set of coefficients for combining board features in a linear polynomial evaluation function.

Performance Element: Uses the learned evaluation function to rank plausible moves for a given board position.

Instance Selector: Reads instances from a list of pre-defined game-board/recommended-move pairs.

Critic: Evaluation - examines the ranking given to the book move by the performance element. Diagnosis - suggests that the book move should be ranked above all other moves.

Learning Element: Adjusts weights of linear polynomial to make move selection correspond to the critic's recommendation.

World Model: Syntax of game board, form and features of linear polynomial evaluation function, method for adjusting evaluation function, and rules of checkers.

LS2:
Purpose: Improve the performance of LS1 by selection of a good set of board features.

Performance Element: LS1.

Instance Selector: The entire set of possible training instances is simply passed to LS1 (via the blackboard).

Critic: Evaluation - analyses the learning ability of LS1 (i.e., the LS2 performance element) with the current set of evaluation
function features. Diagnosis singles out features which are not useful; Therapy selects new features from a predefined list to replace useless features;

Learning Element: Redefines the current set of features as recommended by the critic.

World Model: The LS1 world model, plus the set of features which may be considered, and the performance standard employed by the LS2 critic.

---

Poker Player, Waterman [353]

Purpose: Learn a good strategy for making bets in draw poker.

Environment: Set of all legal poker game states.

Performance Element: Applies the learned production rules to generate actions in a poker game, e.g., bets.

Instance Selector: Selects each game state derived by play against an opponent as a training instance.

Critic: Two versions of the program use two different critics. In both cases the critic performs the following functions:

Evaluation - decides whether the poker bet made by the Performance Element was acceptable. Diagnosis - gives important state variables for deciding the correct bet. Therapy - provides the bet which the Performance Element should have made. In "explicit" learning the critic is an expert poker player, either human or programmed. In "implicit" learning, the evaluation and therapy are deduced from the next action of the opponent and a set of predefined axioms, while diagnosis is read from a predefined "decision matrix".

Learning Element: Modifies and adds production rules to the system. Mistakes are corrected by adding a new rule in front of the rule responsible for the incorrect response.
World Model: Rules of poker, features used to describe the game state, the language of production rules, heuristics for updating the rule base, the model of an opponent.

---------------

Model Reference Adaptive Control, e.g. Landau [17]
Domain: Control Systems.
Purpose: Construct a "controller" which preprocesses inputs to an existing system (called the "plant"). The behavior of the combined controller-plant system is to mimic the behavior of a third system (called the "reference model") on the training data.
Environment: The plant to be controlled, and the set of possible inputs (including disturbances).
Performance Element: The controller - a system whose output is used as input to the plant. Its behavior is a function of the input signal, past I/O behavior of the plant, and a set of adjustable parameters.
Instance Selector: Accepts data sequence (as input to the controller) from the environment.
Critic: Evaluation - applies a measure of performance which is some function of the arithmetic difference between the plant and reference model outputs. In some cases the reference model is mathematically defined, and can therefore be considered part of the critic. In other cases the reference model is an actual system, and is considered part of the environment.
Learning Element: Modifies the parameters of the performance element (controller), depending on the performance measure supplied by the critic.
World Model: Control theory assumptions (time invariance, linearity, etc.) and techniques, and the standard of performance embodied in the critic.
